

Atmospheric scale heights of red giants probed with Amber

Tijl Verhoelst, Pieter Deroo, Clio Gielen

Scientific rationale:

Larger context: determination of fundamental stellar parameters (T_{eff} , diameter, luminosity, spectral type)

Why study atmospheres?

- every photon of stellar light comes from an atmosphere
- spectral and spatial information on stars appearance: lines, limb darkening, photocenter shifts,...

Why red giants?

- effects especially strong in giants
- not yet fully understood

Additional importance:

- use for interferometric calibration: MIDI and AMBER calibrators

Immediate objective:

Derive diameters and limb darkening as a function of wavelength for a sample of well-known late-G, K and M giants (from MIDI calibrator list)

AMBER instrument because of spatial resolution and suitability of K-band (molecular bands, i.e. CO and H₂O, but no dust)

Selection criteria aimed at efficiency and homogeneity:

- 1 AT configuration for all objects
- baseline configuration to probe first lobe, first zero and second lobe simultaneously (including differential phase)

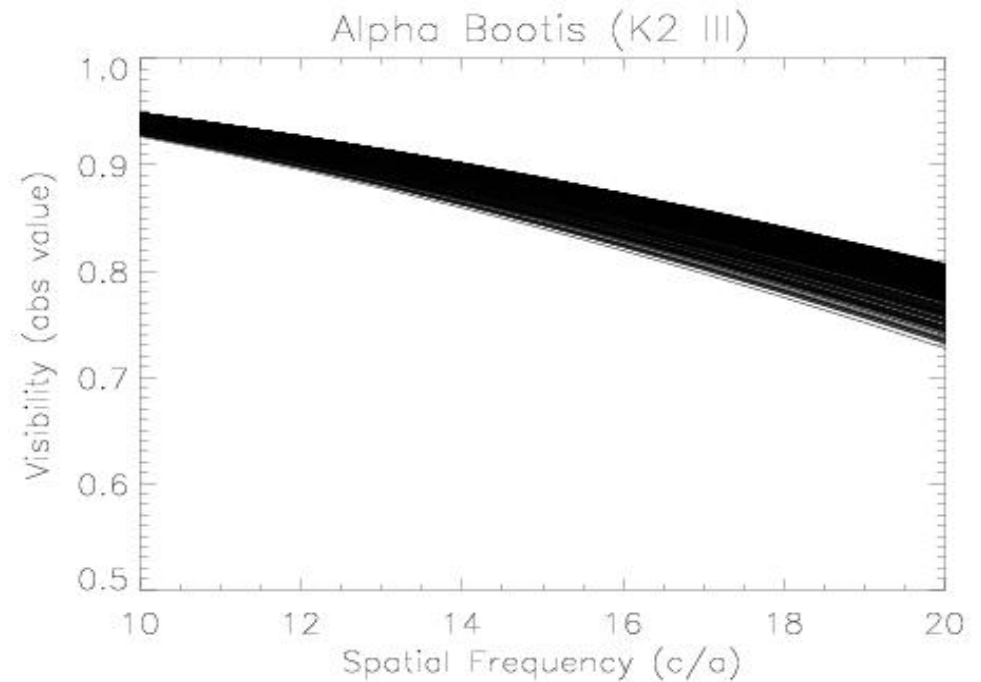

One visibility point per target

No schedule constraints (dark moon, part of the night)

Instrument setup:

- AMBER low resolution (JHK)
- Baselines:
 - D0-G1-J6 (71.6-148.8-192.3 m)
- required accuracy: few percent

Science targets and calibrators: hot and unresolved calibrators

science	calib	dist(°)	diam(mas)	vis	Kmag	spec.type
HD25470	HD33262	11.1	0.95	0.82	3.37	F7V
HD6311	HD15008	8.3	0.52	0.94	3.96	A3V
HD62082	HD62412	4.0	0.96	0.82	3.54	K1III
HD74167	HD75063	1.3	0.61	0.93	3.63	A1III

Total observing time:

- 45 x 1-2 hour = 45-90 hours → large programme

Observing period:

- two observing periods necessary (P80-P81)
